

Acid rain

Acid rain is a big problem that destroys the environment. The issue appeared as a result of the development of industry and motorized transport. Factories and cars produce acid substances that get to the atmosphere. The substances react with water in the air and then the acid rain falls to the ground. That rain destroys monuments and forests. In the polluted water fishes are dying and many people have a respiratory disease because of "smog" (a poisonous fog). We can reduce acid rain when we use less fuel. For example: don't go by car to school or work. Ride a bike or go by train!;
